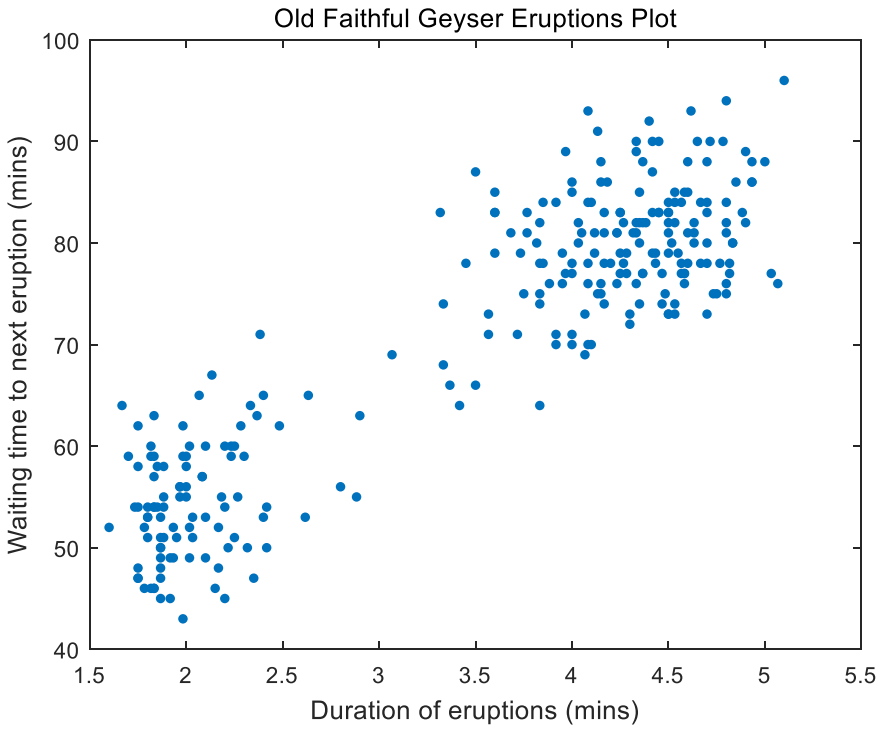
EE511 Project 3

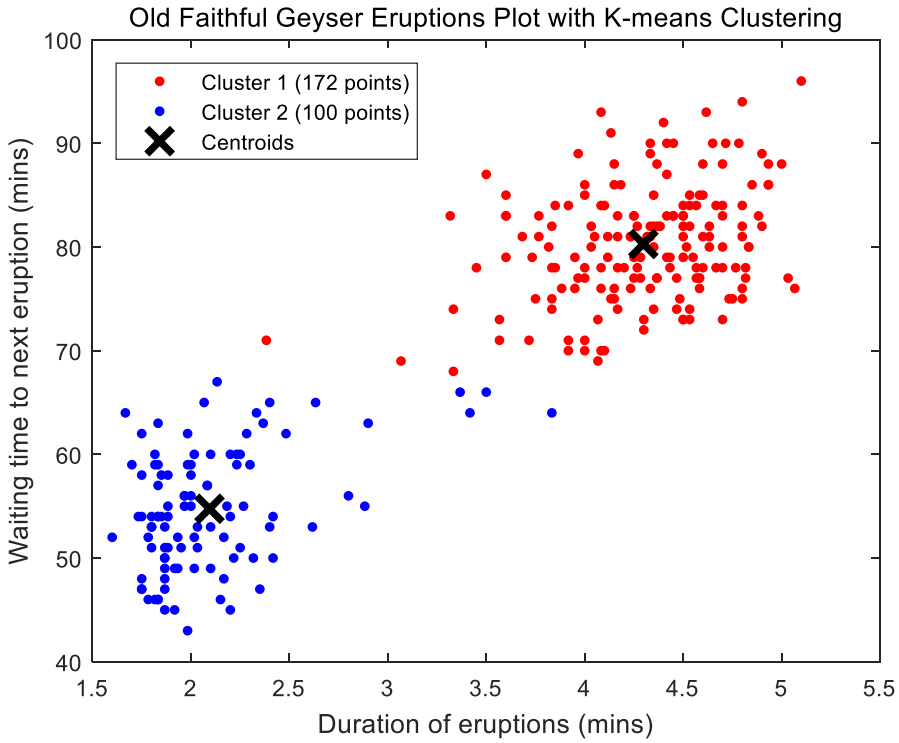
This project is implemented using MATLAB. Codes are attached in the end of this document.

[Testing Faith]

In this problem, I use textscan function to read data from text files and convert to a 272 by 2 matrix. The first column is duration of eruption and the second column is the waiting time to next eruption. Then generate the scatter plot as following.

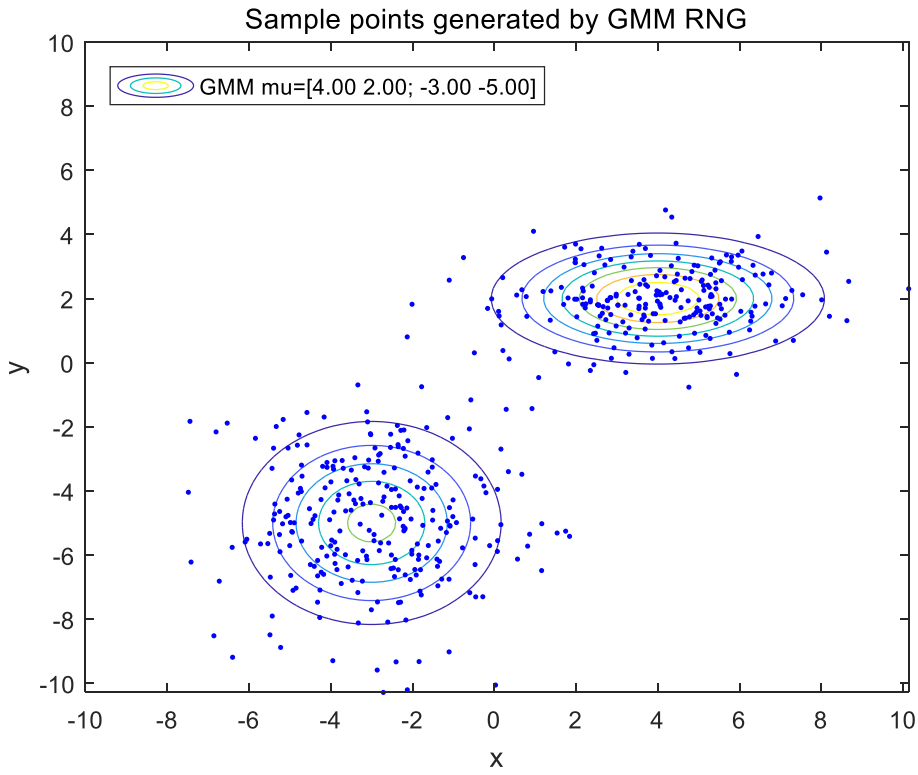


Then use k-mean clustering function to partition the data into two clusters (k = 2). This k-means function uses the squared Euclidean distance measure and the k-means++ algorithm for cluster center initialization. The number of points in cluster and centroids keep the same in each run.



[EM]

GMM RNG with 2 subpopulations:
The below plot is the contour of pdf and sampling points generated by this RNG.
The original parameters of pdf used by this RNG are listed on right side.



Original PDF Parameters

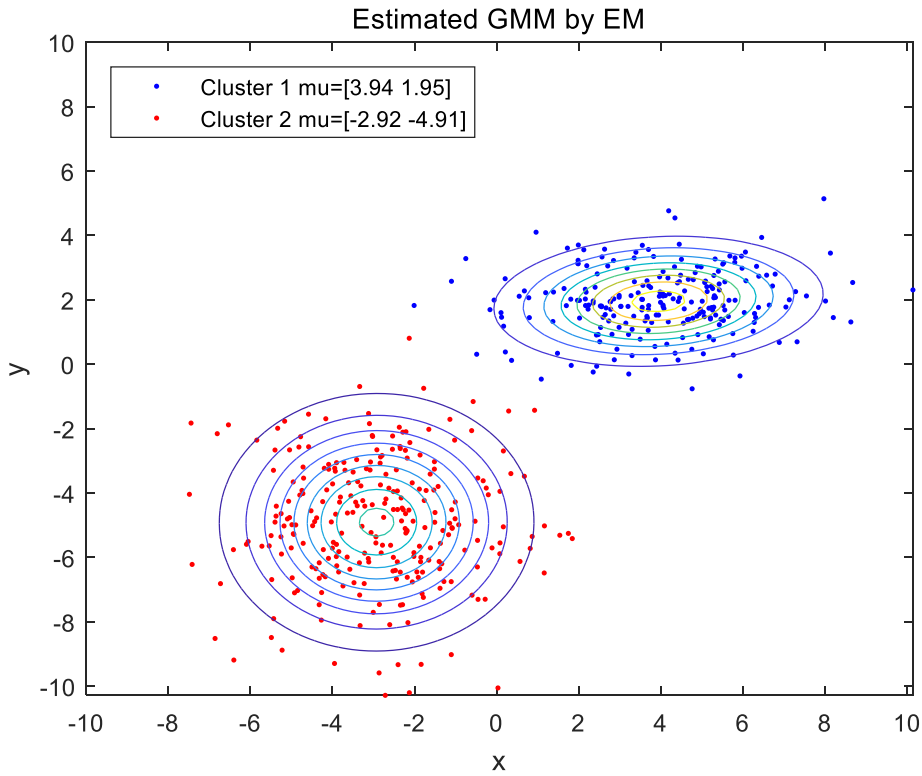
$$\text{Mu} = \begin{matrix} 4 & 2 \\ -3 & -5 \end{matrix}$$

$$\text{Sigma 1} = \begin{matrix} 4 & 0 \\ 0 & 1 \end{matrix}$$

$$\text{Sigma 2} = \begin{matrix} 3 & 0 \\ 0 & 3 \end{matrix}$$

$$\text{P} = \begin{matrix} 0.5 & 0.5 \end{matrix}$$

Then use expectation maximization (EM) algorithm to estimate the pdf of sampling points. The below plot is the contour of estimated pdf. The estimated parameters are listed on right side. Comparing with original parameters and the shape of pdf, the parameters and shape conform to the original approximately.



Estimated Parameters of GMM

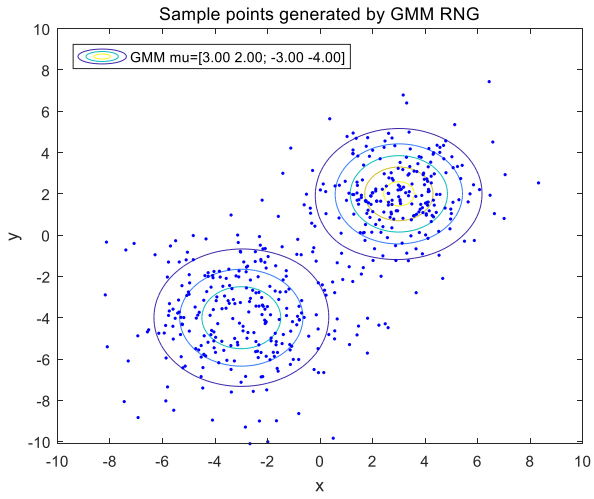
$$\text{Mu} = \begin{matrix} 3.94 & 1.95 \\ -2.92 & -4.91 \end{matrix}$$

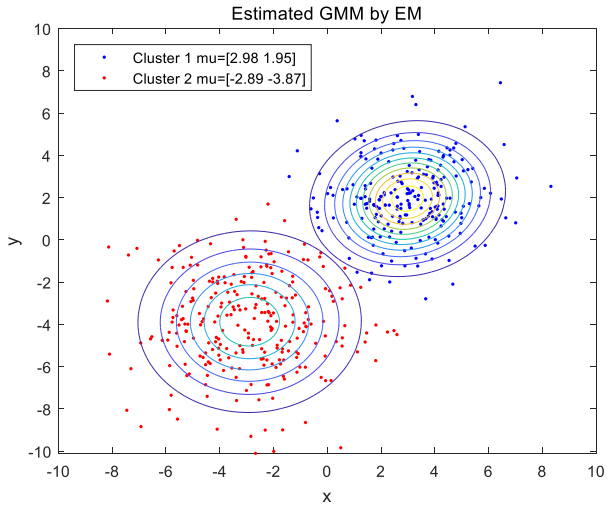
$$\text{Sigma 1} = \begin{matrix} 3.75 & 0.21 \\ 0.21 & 0.95 \end{matrix}$$

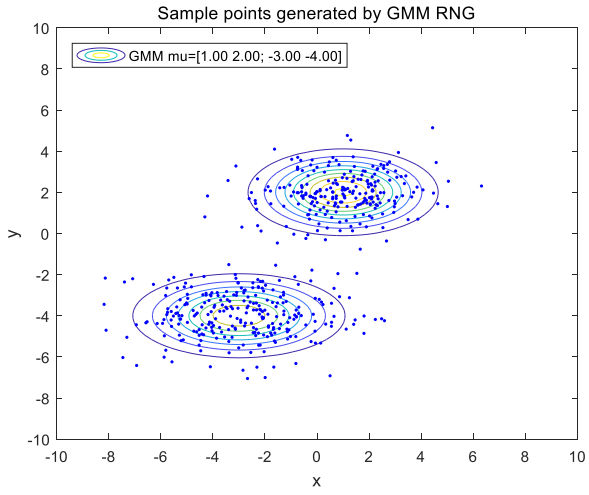
$$\text{Sigma 2} = \begin{matrix} 3.30 & 0.01 \\ 0.01 & 3.59 \end{matrix}$$

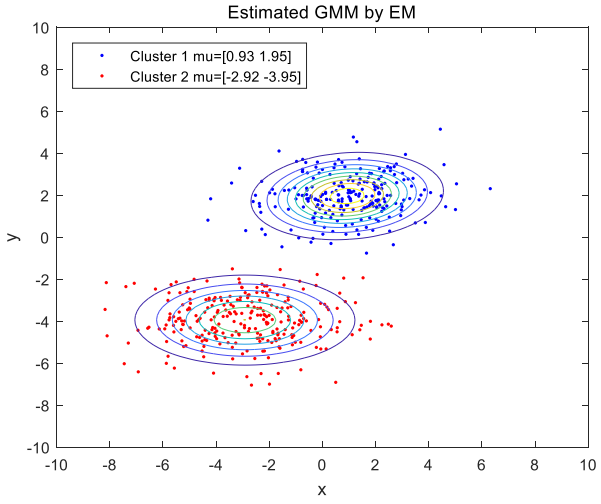
$$\text{P} = \begin{matrix} 0.47 & 0.53 \end{matrix}$$

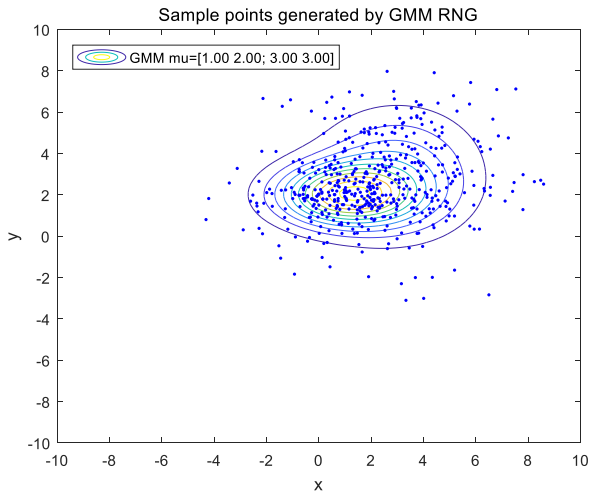
The following plots are estimated pdf of spherical covariance matrices, ellipsoidal covariance matrices and poorly-separated subpopulations. Left side are original pdf and right side are estimated pdf. For the quality, spherical and ellipsoidal covariance are better than poorly-separated. For speed of estimation, spherical and ellipsoidal covariance are much faster than poorly-separated. Spherical and ellipsoidal cases generally take dozens of iterations, but poorly-separated case may take hundreds of iterations.

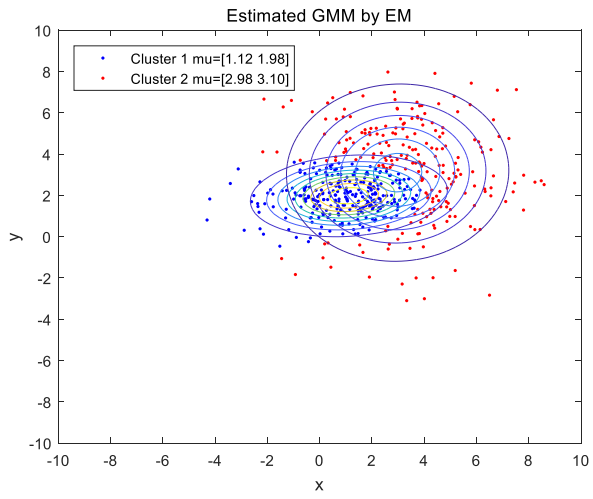




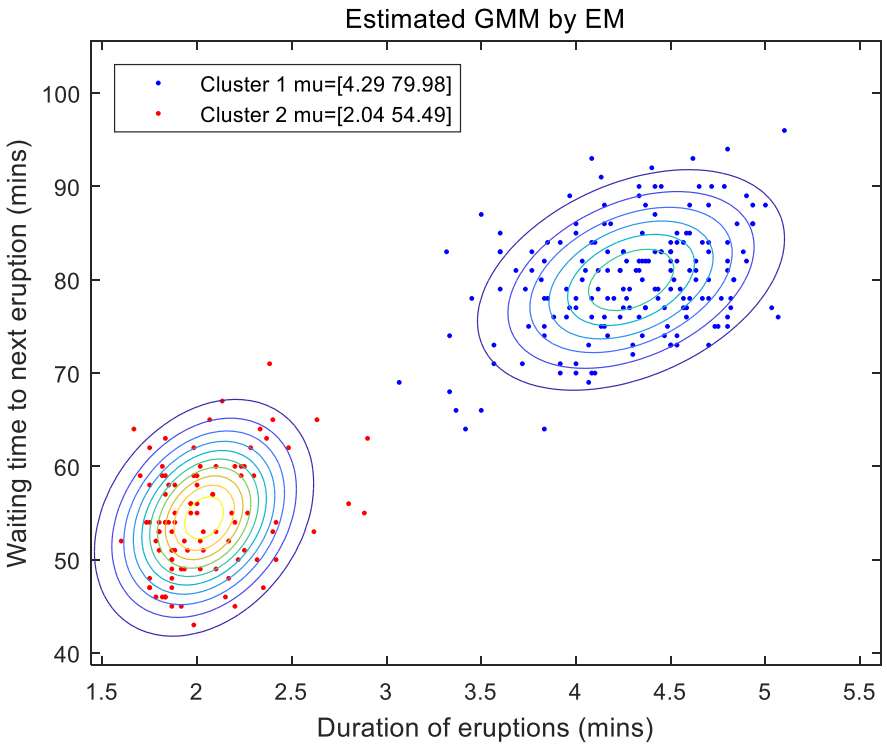








The below plot is the GMM-EM estimation for old faithful data set.



Estimated GMM for Old faithful data

$$\text{Mu} = \begin{matrix} 4.29 & 79.88 \\ 2.04 & 54.49 \end{matrix}$$

$$\text{Sigma 1} = \begin{matrix} 0.17 & 0.93 \\ 0.93 & 35.88 \end{matrix}$$

$$\text{Sigma 2} = \begin{matrix} 0.07 & 0.44 \\ 0.44 & 33.77 \end{matrix}$$

$$\text{P} = \begin{matrix} 0.64 & 0.36 \end{matrix}$$

[Clusters of Text]

I tried different k values and record the average distance to centroid within cluster. The below plot it the relationship between k value and average distance to centroid with cluster. I choose k = 12 because the average distance changes little when k goes greater than 12.
